

GameCult / Epiphany / Bifrost

Integrated Investment Dossier

Diligence memo, product thesis, risk map, and staged proof plan

Prepared for: Internal venture partner discussion

Prepared on: May 30, 2026

Status: Discussion draft, not legal or tax advice

Format: Compile-ready L^AT_EX source with footnote citations

Core thesis. GameCult is an early, founder-led attempt to turn agent-assisted work into an inspectable production system. Epiphany addresses persistent agent context and execution; CultMesh addresses typed distributed state; Bifrost addresses work intake, governance, receipts, credit, and eventual reward flows. The investable question is not whether the vision is large. It is whether this stack can repeatedly produce accepted external work with lower coordination cost than a conventional team, agency, or enterprise workflow platform.

Confidential. All projections are scenario analysis. Public-source diligence remains incomplete. Definitive investment terms require counsel, technical diligence, nonprofit governance review, and founder confirmation.

List of Tables

Executive Summary

Recommendation

Proceed to founder meeting and legal/technical diligence only as a staged proof exercise. The public materials justify a serious look, not a priced conviction. The first financing conversation should focus on whether GameCult can prove a repeatable external work loop: request intake, agent execution, human review, accepted artifact, receipt, cost accounting, and contributor credit.

Recommended capital package. Consider a small diligence/proof tranche first, with a larger \$3M-\$5M commitment only after entity/IP review, working product demonstration, and evidence that Bifrost is becoming the canonical work/receipt layer for external swarm activity. Later capital should be tied to accepted work per human review hour, design-partner usage, security posture, and compute economics.

One-sentence thesis

GameCult is building infrastructure for governed human/agent work: **Epiphany** coordinates persistent agent execution, **CultMesh** distributes typed state, and **Bifrost** records work, discussion, receipts, credit, and potential reward flows.

Why this may matter

The narrow version is an AI developer workflow product: persistent agents that can work across complex repositories without losing the plot. The broader version is a work-governance platform: humans and agents propose work, prioritize it, execute it, verify outputs, record receipts, and attach credit or rewards. GameCult's front page frames the organization around open development, visible work, legible incentives, contributor standing, and a cooperative model in which supporters and builders shape priorities and policy.¹

Bifrost is the main evidence that this is more than agent rhetoric. Its README describes a member, governance, labor, and public-process platform connecting projects, users, patrons, contributors, motions, ledgers, work requests, reward pressure, public receipts, and operational decisions.² The jurisdiction map describes the economic loop: users, patrons, members, agents, or contributors identify work; the community expresses priority; reward pressure rises; contributors claim work; maintainers accept artifacts; and Bifrost credits the contributor and records reward allocation.³

¹GameCult front page: <https://gamecult.org/>

²GameCult/Bifrost README: <https://github.com/GameCult/Bifrost/blob/main/README.md>

³Bifrost jurisdiction map: <https://github.com/GameCult/Bifrost/blob/main/docs/jurisdiction-map.md>

Bottom line

The investable object is not the current game portfolio. It is the possibility of a repeatable human/agent production loop. This should be sold internally as high-risk infrastructure, closer to enterprise workflow, developer tooling, and labor-market plumbing than to a foundation-model company. If it works, upside can be large. If it does not produce measurable external work, the broader vision is not yet investable.

Primer for Nontechnical Partners

1.1 What is an AI agent?

A modern AI agent is a language model connected to tools. Instead of simply answering a question, it can inspect files, run commands, search documents, write code, create issues, comment on pull requests, or communicate with other agents. The current generation is powerful, but fragile. Agents often lose context, repeat work, hallucinate explanations, make plausible local changes while the global design has drifted, and lack a reliable institutional memory.

The current state of the market is therefore not solved by adding more prompts. The hard problem is **coordination**: what does the agent believe, what evidence changed that belief, who gave it authority, what part of the work is private, what can be published, who verifies output, who gets credit, and how does the system remember across days or months?

1.2 What is different about GameCult?

GameCult appears to be building an organization where agents are not just assistants but part of the operating structure. Each repo can have a **Face**, a public/social agent identity. VoidBot reads Discord and repo context. Epiphany externalizes typed project memory. CultMesh supplies distributed typed state. Bifrost turns requests, discussion, work, reviews, receipts, and rewards into governed records.

In ordinary terms: instead of treating AI as a chatbot bolted onto a team, GameCult is trying to make agent work auditable, repeatable, and connected to governance. The mythology around the Colossus is unusual and should not lead investor materials. The underlying engineering goal is legible: preserve context, assign authority, verify work, and record who did what.

1.3 What is the state of the art today?

For a lay partner, today's landscape has four imperfect pieces:

1. **AI coding assistants** help individual developers write code faster, but usually do not own durable organizational memory or governance.
2. **Autonomous coding agents** can attempt larger tasks, but often struggle with context, verification, and safe authority boundaries.
3. **Freelance and work platforms** match buyers to human labor, but rarely convert small ideas, critique, testing, or governance participation into durable economic credit.
4. **DAOs and web3 governance systems** can coordinate money and votes, but often lack robust real-world work execution, review discipline, legal compliance, and human-support infrastructure.

GameCult's proposed synthesis is different: **AI-native work governance**. The system is not only supposed to route tasks. It is supposed to let humans and agents cooperate, remember

decisions, verify output, assign credit, and eventually support rewards. That is a plausible product category, but it must prove a hard enterprise habit: buyers and maintainers have to trust the workflow enough to route real work through it.

1.4 Why housing and social support matter

Housing and social support are a later-stage thesis, not a near-term proof point. The ILO's 2024-26 social protection report states that 3.8 billion people remain entirely unprotected from life challenges and climate impacts, while social protection supports human development, productive investment, and livelihood diversification.¹ The UN's 2024 SDG 11 report states that 1.12 billion people lived in slums or informal settlements in 2022 and that nearly 70 percent of the global population is projected to live in cities by 2050, making affordable housing and essential services imperative.²

For GameCult, the business logic is that stability can increase contribution capacity. But this should remain a measured pilot hypothesis until the basic work loop is proven. Housing, internet access, education, and support benefits should be framed as possible contributor-development programs, not as evidence of enterprise value today.

²UN SDG 11 report 2024: <https://unstats.un.org/sdgs/report/2024/Goal-11/>

The GameCult Stack

2.1 Epiphany: persistent agent cognition

Epiphany is the control-plane thesis. Its README says Epiphany is an opinionated fork of Codex built around the demand that the model must model the thing it is changing. It moves important state out of transcript fog and into typed, inspectable surfaces such as maps, evidence, retrieval state, graph/frontier state, churn pressure, and compact reflections.¹

The implementation plan lists durable Epiphany state, bounded prompt integration, semantic retrieval, explicit indexing, typed mutation, distillation, proposal, verifier-backed promotion, role launch/result/accept, reorientation, CRRC, job bindings, runtime-spine documents, CultMesh integration, and operator surfaces.²

2.1.1 Why it matters

The failure mode of current agents is not that they cannot write code. It is that they cannot reliably preserve global coherence. Epiphany's product wedge is therefore not simply faster coding. It is persistent organizational cognition for agents.

2.2 VoidBot and Faces: the social interface

VoidBot is the social and Discord-native interface into the swarm. It can answer from archived Discord history, indexed GameCult repos, and Aetheria lore, and then hand deeper work off to Codex. It supports real Discord replies, semantic retrieval, source/lore indexing, interaction memory, and Codex handoff flows.³

This matters because work does not originate only in tickets. It originates in chat, argument, taste, frustration, social trust, and repeated community pressure. VoidBot and repo Faces are the layer where that signal becomes visible.

2.3 CultMesh: typed distributed state

CultMesh is documented as the distributed realtime database and simulation-consensus layer for GameCult projects. It sits over CultCache for typed documents and local persistence, and over CultNet for transport and schema-v0 messages.⁴

¹GameCult/Epiphany README: <https://github.com/GameCult/Epiphany/blob/main/README.md>

²Epiphany fork implementation plan: <https://github.com/GameCult/Epiphany/blob/main/notes/epiphany-fork-implementation-plan.md>

³GameCult/VoidBot README: <https://github.com/GameCult/VoidBot/blob/main/README.md>

⁴CultMesh README: <https://github.com/GameCult/CultLib/blob/main/src/GameCult.Mesh/README.md>

CultMesh's Verse model is important. A Verse is described as a rule-bearing consensus graph with authority models, compatibility/rules hashes, discovery endpoints, authority runtimes, parent Verse support, peer exchange, and authority leases.⁵

For a lay audience, CultMesh is the connective tissue. It makes it possible for multiple local systems to share typed state without pretending that all data has the same privacy, authority, or governance status.

2.4 Bifrost: governance, work, rewards, receipts

Bifrost is the economic center. Its README says it is the planned member, governance, labor, and public-process platform under the Yggdrasil infrastructure umbrella. It connects projects, users, patrons, contributors, motions, ledgers, work requests, reward pressure, public receipts, and operational decisions.⁶

The repository already contains an alpha foundation slice: ASP.NET Core app, PostgreSQL-backed EF Core model, GitHub OAuth sign-in, invite/approval membership gating, roles, a work board, motions, ledgers, GitHub webhook ingestion, bridge tooling for agent-owned GitHub draft PRs and Discord posts, CultCache-backed governance topics, CultCache/CultNet-backed agent intake, Docker smoke tests, and xUnit tests.⁷

2.4.1 Bifrost's labor model

The full implementation strategy aligns Bifrost with a labor platform concept: contributor history, governance, work priority, reward pressure, contribution points, patron points, decay, and revenue share. It states that accepted work becomes contributor credit plus reward allocation, and that contribution points, patron points, decay, and revenue share should be first-class product systems rather than spreadsheet afterthoughts.⁸

2.5 Heimdall: identity and capability layer

Bifrost's jurisdiction map says Heimdall owns OAuth provider flows, account linking, credential custody, signed identity and capability claims, grants, consent, revocation, and capability evaluation. Bifrost consumes Heimdall claims and governs public work crossings; Heimdall decides who may cross under which grant.⁹

This split matters. A global labor and payout network cannot treat identity as an afterthought. It needs auditable human and agent identity, permission, consent, and revocation.

⁹Bifrost jurisdiction map, ownership boundaries: <https://github.com/GameCult/Bifrost/blob/main/docs/jurisdiction-map.md>

2.6 Proof workloads: Fensalir, Mimir, AquaSynth, Ghostlight, Aetheria

GameCult’s surrounding projects are not random. They are stress tests for the stack.

- **Fensalir** tests engine/runtime/rendering/audio field machinery. Its README describes a native C# runtime and field engine with D3D12 frame ownership, hot reload, PCM audio, debug UI, volumetric fields, fractal geometry, temporal evidence, and synth-backed sound.¹⁰
- **Mimir** attempts to make a room computable by synchronizing cameras, microphones, speakers, loopbacks, and network feeds into a coherent OBS-facing program surface.¹¹
- **AquaSynth** is a synth and vocal-tract experiment. Its IPA roadmap describes a path from IPA text to phonetic tokens, articulatory gesture plans, morphology-specific tract/excitation curves, Faust DSP, and nonhuman speech/song/chant rendering.¹²
- **Ghostlight** explores socially persistent generative agents and character-driven generation.¹³

These projects create the internal pressure needed to prove that Epiphany, Bifrost, and CultMesh can handle real complexity.

Diligence Findings

3.1 Verified from public materials

Area	Finding
GameCult mission	Public front page emphasizes open development, legible incentives, bounty-driven contribution, contributor standing, and cooperative participation.
Bifrost	Repo contains a working alpha foundation slice: web app, database model, GitHub auth, membership gating, work board, motions, ledgers, GitHub webhooks, bridge tooling, CultCache topics, and agent intake.
Bifrost economics	Documentation defines contributor points, patron points, decay, voting weight, revenue-share calculation, and payout proposal batches.
Bifrost jurisdiction	Bifrost owns governed public crossings: GitHub/Discord/CultNet/CultCache work transport, receipts, priority, and audit.
Epiphany	Public docs show a persistent typed-state agent control plane with role separation, verification, promotion, reorientation, runtime-spine, and CultMesh direction.
CultMesh	Public docs define distributed typed state, Verse discovery, peer exchange, authority leases, shard logs, replica catch-up, and witness consensus.
Surrounding projects	Fensalir, Mimir, AquaSynth, Ghostlight, and related repos serve as complex proof workloads.

3.2 Not yet verified

- Actual nonprofit legal status, entity form, bylaws, board structure, and whether there is an affiliated for-profit entity.
- Founder identity, IP assignment, contributor agreements, and cap/economic rights table if any.
- Real usage, revenue, donations, grants, or community scale beyond public GitHub/site evidence.
- Private Discord activity and actual agent swarm throughput.
- Cost per useful agent artifact, accepted output rate, and human review burden.
- Compliance posture for payments, rewards, revenue share, housing, stipends, cross-border support, KYC/AML, tax, and labor classification.
- Third-party license exposure across repos and model-provider terms.

3.3 Current diligence rating

Dimension	Rating	Comment
Technical ambition	Very high	Evidence supports a coherent and unusually broad stack, but ambition is not product-market proof.
Product maturity	Early	Bifrost is not public alpha; Epiphany remains highly technical and tied to Codex plumbing.
Commercial traction	Unproven	No confirmed revenue or external design-partner adoption.
Moat potential	Conditional	Durable state, governance ledgers, contribution history, and network knowledge can compound if external users adopt the workflow.
Legal complexity	Extreme	Nonprofit structure, rewards, housing, social support, and agent labor require careful design.
Founder dependency	High	Architecture appears founder-led and culturally specific.
Asymmetric upside	Meaningful but unpriced	If Bifrost/Epiphany/CultMesh scale, the ceiling may exceed normal devtool outcomes; current evidence supports diligence, not valuation enthusiasm.

Economic Context and Market Map

4.1 The size of the opportunity

The World Bank tracks global GDP in current US dollars through 2024, and the global economy is measured in the \$100T+ range.¹ That number is useful only as background. GameCult should not be pitched as if a tiny fraction of global GDP is automatically available. The realistic initial market is narrower: developer workflow, AI-assisted software services, enterprise knowledge-work automation, and governance/compliance tooling for organizations that need auditable agent activity.

That means the competitive frame is not only OpenAI or other model vendors. It also includes enterprise workflow and integration vendors, consulting firms, systems integrators, RPA platforms, IT service-management tools, developer-platform companies, and large incumbents such as Oracle, Microsoft, ServiceNow, Atlassian, GitHub, and Salesforce. The opportunity is real, but the buyer expects reliability, integration, compliance, procurement fit, and support. The machine has to do more than sound inevitable. It has to survive a procurement meeting with someone paid to say no.

4.2 Initial wedge

The most credible wedge is a measured external-work loop for complex repositories and technical organizations:

- external team submits a scoped engineering, documentation, research, or workflow problem,
- Bifrost records scope, consent, priority, and discussion,
- Epiphany performs bounded agent work with visible cost and role accounting,
- maintainers accept, reject, or request changes,
- Bifrost records receipts, contributor credit, and lessons learned,
- the customer sees whether the result reduced human coordination cost.

If this loop works, the first commercial product can be a managed agent-work platform or service for software organizations with hard repositories, backlog pressure, and documentation debt. Broader labor-network claims should wait until this proof exists.

4.3 What must be proven

The diligence bar should be concrete:

- accepted useful work per human supervisor hour,
- cost per accepted artifact, including model spend and review time,

¹World Bank GDP current US\$ - World: <https://data.worldbank.org/indicator/NY.GDP.MKTP.CD?locations=1W>

- repeatability across repos not authored by GameCult,
- security boundaries for secrets, private context, and external writes,
- buyer willingness to pay for the workflow rather than the story,
- evidence that Bifrost records reduce coordination burden instead of becoming another administrative layer.

4.4 Why current labor markets miss value

Existing global labor platforms largely require a worker to present a coherent resume, bid for a job, perform a defined task, and deliver a recognizable artifact. That misses many useful signals:

- a good idea from someone without credentials,
- a useful bug report,
- local cultural knowledge,
- translation, testing, critique, and moderation,
- design taste and aesthetic judgment,
- a governance objection that prevents wasted work,
- agent steering or review,
- evidence that a proposed direction is wrong.

Bifrost may be able to make these signals legible. Epiphany may be able to turn some of them into artifacts. CultMesh may let useful state travel without collapsing private information into public truth. Each claim needs measurement. In the near term, the useful question is not “can every contribution become part of a global labor market?” It is “can the system capture enough neglected signal to produce better accepted work than a normal issue tracker plus a coding assistant?”

4.5 Why social security and housing are in scope

The ILO frames social protection as an enabler of productive investment, livelihood diversification, human development, and resilience.² The UN housing data shows that the lack of adequate housing remains a massive global bottleneck.³

If Bifrost can identify promising contributors and route them into agent-amplified work, then support programs may become investments in contributor uptime and economic output. This belongs in a later pilot. It should not be used to justify early valuation.

²ILO social protection report key messages: <https://www.ilo.org/publications/flagship-reports/world-social-protection-report-2024-26-universal-social-protection-climate>

³UN SDG 11 housing and slum data: <https://unstats.un.org/sdgs/report/2024/Goal-11/>

Proof Economics

5.1 Near-term operating model

The central economic claim is modest at first: the network should increase accepted output per human coordinator hour. That is the number a serious buyer, partner, or funder can understand.

Proof metric. Useful output = accepted artifacts / (human review hours + operator hours + model spend converted to dollars). The first proof should show whether GameCult can beat conventional engineering support, consulting, or internal automation on a defined class of work.

- **Agent leverage:** Epiphany turns scoped intent into tasks, artifacts, PRs, research, tests, and summaries.
- **Governance leverage:** Bifrost records scope, consent, priority, receipts, and credit so work can be audited.
- **Memory leverage:** typed state and retrieval reduce repeated context-loading and repeated mistakes.
- **Market leverage:** design partners supply real external problems, constraints, and willingness-to-pay evidence.

5.2 Illustrative annual service scenarios

Scenario	Customers / partners	Annual revenue per account	Annual revenue run-rate
Proof pilots	3-10	\$0-\$25,000	\$0-\$250,000
Design partners	10-30	\$25,000-\$100,000	\$250,000-\$3M
Managed agent-work service	50-150	\$50,000-\$250,000	\$2.5M-\$37.5M
Enterprise workflow platform	100-500	\$100,000-\$500,000	\$10M-\$250M
Large infrastructure outcome	500+	\$250,000-\$1M+	\$125M-\$500M+

These are not forecasts. They are sanity bands for a B2B or managed-services path. A single-digit-billion outcome is plausible only if the company becomes a trusted infrastructure layer or a high-margin service platform. Larger outcomes require broad adoption, strong retention, enterprise-grade integrations, and a durable data/workflow moat.

5.3 Later network flows

A mature Bifrost network might eventually route more than paid customer work. It could record:

- paid work and bounty/reward allocations,
- patron and member priority boosts,
- housing and rent support flows,
- benefit and emergency grant disbursements,
- project revenue-share flows,
- internal services, education, and tooling,
- contributor-to-contributor service exchange,
- governance-directed capital allocation.

These flows are strategically important but should be treated as options, not valuation evidence. They carry legal, tax, labor, securities, housing, and governance risk. The honest near-term proof remains accepted external work at known cost.

Valuation and Capital Structure

6.1 Separate the numbers

Partners should separate three concepts:

1. **Operating entity value:** the value of any GameCult OpCo, service company, or software subsidiary.
2. **Network capitalization:** the value of treasuries, reserves, housing assets, contributor support funds, protocol claims, cooperative shares, or affiliated vehicles.
3. **Annual gross flow:** the total work, reward, housing, benefit, support, and capital allocation moving through the network.

The base case should not assume venture-scale liquidity unless a commercial entity or revenue contract exists. The upside case should be described through operating revenue, strategic value, and network effects rather than through trillion-dollar aggregate-flow claims.

6.2 Illustrative value scenarios

Case	Annual revenue or funded activity	Value logic	Implied scale
Mission lab	\$0-\$1M	Grants, donations, internal use, proof work	Not a venture return case
Specialized service	\$1M-\$10M	Managed agent work for technical teams	Small business / acquihire / strategic option
Vertical platform	\$10M-\$100M	Repeatable workflow product with strong retention	Venture-relevant if margins and growth are credible
Enterprise infrastructure	\$100M-\$500M+	System of record for governed agent work	Multi-billion possible if defensible
Network institution	Commercial revenue plus governed support/reward flows	Requires legal structure, trust, compliance, and broad adoption	Long-dated option, not current valuation base

The highest cases require GameCult to become more than a clever internal agent stack. It must become a trusted system of record for work, identity, audit, contribution, and rewards. That is an Oracle-class or ServiceNow-class integration problem as much as an AI problem.

6.3 Equity-like value if nonprofit

If GameCult is a nonprofit, ordinary equity ownership may be impossible or inappropriate. The capital return may need to come from:

- an affiliated taxable service company,
- a public benefit corporation subsidiary,
- a recoverable grant or mission-related loan,
- a revenue participation agreement with a commercial services arm,
- a licensed enterprise distribution entity,
- impact-return structures tied to verified network revenue rather than control of the nonprofit.

The IRS states that to be tax-exempt under section 501(c)(3), an organization must be organized and operated exclusively for exempt purposes and none of its earnings may inure to any private shareholder or individual; it also must not operate for private interests.¹ Therefore any capital plan must avoid private inurement, excessive private benefit, or investor control inconsistent with the nonprofit's mission.

¹IRS exemption requirements for 501(c)(3) organizations: <https://www.irs.gov/charities-non-profits/charitable-organizations/exemption-requirements-501c3-organizations>

Scaling Strategy

7.1 Strategic goal

The immediate goal is not to launch the full social vision. The goal is to prove a repeatable loop:

Human or agent identifies work → Bifrost records scope/priority → Epiphany decomposes and executes → Maintainers review artifacts → Bifrost records receipts and credit → Metrics show cost, review load, and accepted output.

7.2 Phase 1: Bifrost-first private alpha

Within 90-120 days, Bifrost should be the canonical surface for governed external swarm tasks. Discord may mirror. VoidBot may observe. Epiphany may execute. But Bifrost owns topics, work items, dispatch packets, receipts, credit, and reward pressure.

Milestones:

- Bifrost deployed privately on Yggdrasil or equivalent infrastructure.
- GitHub sign-in and member gating live.
- Governance topics and work items used for all external swarm tasks.
- Agent transport requests visible inside Bifrost.
- Receipts attached to originating topics/work items.
- Cost and review-time fields captured for every task.

7.3 Phase 2: Public proof sprint

Run a compute-subsidized proof campaign, but route every task through Bifrost. The offer should be simple: submit a stuck repo, tool, documentation problem, research task, or prototype request; the swarm will attempt selected tasks and publish what happened when permission allows. Public case studies are useful, but private design-partner evidence also counts if the metrics are available for diligence.

Every run should record:

- scope and consent,
- Bifrost topic/work item,
- agent roles and model spend,
- human review hours,
- artifacts produced,
- accepted/rejected outcome,

- lessons added to memory,
- public case-study permission.

7.4 Phase 3: Design partners

Convert proof-sprint participants into 10-30 design partners. Their job is to prove that Epiphany and Bifrost work on external repos and organizations without requiring every user to internalize GameCult's internal language.

Core metric: **accepted useful work per human supervisor hour.**

7.5 Phase 4: Bifrost Valkyries

Launch a 12-month Valkyries program only after the external work loop is producing measured results. In investor-facing terms, this is a contributor-support cohort: selected contributors receive stability support, agent access, and review capacity while Bifrost measures whether that support increases accepted output.

Illustrative pilot:

- 100 Valkyries across 3-5 low-cost regions.
- \$300-\$800/month in total support per fellow.
- Epiphany access, mentor/reviewer support, contribution board, and Bifrost ledger.
- Monthly output measurement and cohort reporting.

7.6 Phase 5: Housing/support pilots

Housing should not sit directly on the main nonprofit balance sheet without counsel. Use sidecars, local partners, community land trust structures, or housing SPVs. Bifrost can record eligibility, contribution history, governance decisions, and support flows, but real estate risk should be separated from the software/governance layer. This is a later experiment, not a near-term investor proof.

Investment / Capital Structure for a Nonprofit Ecosystem

8.1 Why ordinary VC terms do not map cleanly

If GameCult is a nonprofit, there may be no equity, no common stock, no ordinary board seat for economic investors, and no conventional exit. A partner memo must therefore avoid pretending that a normal Series Seed term sheet can simply be dropped on the organization.

Instead, we should negotiate a **capital compact**: a mission-aligned agreement that funds the work, protects the founder's nonprofit/social mission, and gives the investor continued funding discretion, information rights, audit rights, and governance visibility.

8.2 Possible structures

Structure	Use case	Investor economics
Restricted grant	Pure mission funding, no return expectation	Reputation, impact, future relationship; no direct financial return
Recoverable grant	Capital returns only if revenue/surplus occurs	Principal recovery and capped surplus participation, if legally permissible
Program-related or mission-related investment	Foundation/impact-capital structure	Low-interest loan, recoverable capital, or mission-aligned note
Revenue participation agreement	Commercial activity exists but equity is unsuitable	Percentage of approved commercial revenue until cap is reached
For-profit subsidiary / PBC	Enterprise Epiphany/Bifrost services need commercial scaling	Investor buys equity in subsidiary; nonprofit retains mission/possibly IP control
Service company license	Nonprofit owns core mission/IP; affiliate sells enterprise services	Investor participates in affiliate economics
Housing SPV	Real estate/support pilots need separate risk pool	Asset-backed returns or impact returns through sidecar

8.3 Translation of board rights

A conventional board member right should translate into something like:

- **Capital Steward Observer:** non-voting observer on a Scaling Council or Finance/Infrastructure Committee.
- **Tranche Release Committee:** investor approval required for subsequent funding tranches.
- **Use-of-Proceeds Consent:** investor consent for material deviations from the approved plan.
- **Audit and Reporting Rights:** monthly metrics, ledger access, compute spend, and legal/security reporting.
- **Mission-Safe Protective Rights:** veto over investor-funded tokens, payout systems, housing obligations, and unreviewed revenue-share instruments, without control over ordinary nonprofit mission decisions.

This protects capital without turning the investor into a de facto controller of the nonprofit.

Founder-Aligned Agreement Draft

9.1 Founder receives

- Mission protection: investor acknowledges that GameCult is building a nonprofit/cooperative human/agent labor network, not merely a conventional SaaS company.
- Product and mission autonomy: founder remains the principal technical and cultural steward of Epiphany, Bifrost, CultMesh integration, and GameCult’s internal language.
- Open/public-build protection: investor will not require abandonment of open/source-available culture or public proof reporting.
- Social-uplift authorization: housing, contributor support, education, and benefits pilots are permitted when legally structured and measured.
- No forced for-profit conversion: any for-profit affiliate must preserve nonprofit mission control and avoid private inurement.

9.2 Investor receives

- Tranche control tied to measurable scaling milestones.
- Capital Steward Observer role in a Scaling Council, Finance Committee, or equivalent governance body.
- Monthly and quarterly reporting rights.
- Audit rights for investor-funded compute, Bifrost ledgers, and public proof campaigns.
- Protective consent rights over unreviewed payout, token, revenue-share, housing, or benefit instruments.
- Right to invest in or finance approved commercial affiliates, service companies, or housing SPVs if created.

9.3 Core covenants

1. **Bifrost-first covenant.** All external swarm tasks, public proof runs, design-partner tasks, and contributor reward flows must be represented in Bifrost as topics, work items, dispatches, receipts, completion artifacts, or ledger entries.
2. **No shadow governance.** Discord, VoidBot, repo Faces, and ad hoc scripts may not become durable governance/work/reward authorities.
3. **Compute accountability.** Model spend must be logged against tasks, agents, outcomes, and accepted artifacts.
4. **Contributor-output measurement.** The organization must measure baseline output, support received, agent leverage, accepted artifacts, rewards, and retention.

5. **Safety gates.** No autonomous external write access, private-data export, direct payout, revenue-share instrument, or housing obligation without approved policy and counsel review.
6. **Legal gates.** Securities, labor, tax, KYC/AML, data protection, nonprofit/private-benefit, housing, and cross-border support analysis must precede live global programs.

9.4 Milestone tranches

9.4.1 Tranche 1: formation, diligence, and private build

Release after:

- Nonprofit/entity status verified.
- IP assignment or licensing path documented.
- Contributor/license audit started.
- Bifrost private alpha plan approved.
- Compute budget and public proof plan approved.

9.4.2 Tranche 2: Bifrost alpha and public proof

Release after:

- Bifrost private alpha deployed.
- At least 50 consented external/public proof tasks routed through Bifrost.
- Epiphany usable on at least 3 external or semi-external repos.
- Dashboard reports cost per accepted artifact and human review load.

9.4.3 Tranche 3: design partners and ledger economics

Release after:

- 10+ design partners or 3+ paid/mission-funded pilots.
- 100+ external proof tasks completed or terminally failed with artifacts.
- Contribution ledger alpha live.
- Payout/support model counsel-reviewed.
- CultMesh trusted/local Verse prototype or public-dream prototype live.

Diligence Request List

10.1 Corporate and nonprofit

- Legal entity documents, bylaws, nonprofit filings, tax-exempt status if any.
- Board/trustee composition and governance rights.
- Founder authority and any member/cooperative rights.
- Any affiliate entities, fiscal sponsors, foundations, or service companies.

10.2 IP and licensing

- Repo-by-repo license table.
- Founder IP assignment or license.
- Contributor agreements and contributor list.
- Third-party code and model-output policy.
- Commercial license strategy for source-available components.

10.3 Technical

- Live Epiphany demo on a fresh repo.
- Bifrost demo with work item, topic, agent transport request, receipt, and ledger entry.
- CultMesh demo or status report for Verses and typed document sync.
- VoidBot/Discord swarm demo.
- Compute spend, task output, and accepted artifact metrics.
- Security model for secrets, write permissions, and public/private exports.

10.4 Economic and legal

- Existing revenue/donations/grants/support.
- Legal theory for rewards, points, revenue share, payouts, and support benefits.
- Worker/contributor classification plan.
- KYC/AML/sanctions plan for cross-border payouts/support.
- Housing/support pilot structure.
- Data protection and privacy policy.

Risks and Controls

11.1 Primary risks

Risk	Description	Control
Nonprofit/private benefit	Investor economics may conflict with nonprofit law.	Use recoverable grants, mission loans, commercial affiliates, or counsel-reviewed structures.
Scope explosion	GameCult may keep expanding without product closure.	Tranches tied to Bifrost/Epiphany external proof.
Agent noise	Swarm activity may produce volume without useful output.	Measure accepted artifact per human review hour.
Compute burn	Model spend can become uncontrolled.	Budget caps and cost per artifact reporting.
Governance capture	Bounties, points, and votes can be gamed.	Identity, anti-Sybil, audit, maintainer review, and appeal processes.
Housing dependency	Support can become coercive.	Exit rights, portable records, independent review, no ideological conditions.
Brand risk	“Cult” and Colossus language may alarm partners.	Keep mythos internally; externalize as contributor development and human/agent governance.
Legal complexity	Payouts, revenue share, benefits, and cross-border support are regulated.	Legal gates before live scale.

11.2 Ethical red lines

- No housing or benefits conditioned on ideological conformity.
- No opaque agent-only reputation scoring.
- No punitive withdrawal of basic support for governance dissent.
- No debt bondage, company-town lock-in, or nonportable reputation.
- No public export of private worker/operator/agent context.
- No direct payout or revenue-share instrument without counsel review.

Partner Selling Narrative

12.1 The simple pitch

GameCult has built an internal human/agent workflow around unusually complex technical projects. The asset to test is not any one game or engine. It is the operating system around that work: persistent memory, repo identities, governed work transport, contribution credit, and public receipts.

12.2 Why now

AI agents are improving quickly, but organizations still struggle to trust them with real work. The missing layer is not another chatbot. It is scope control, memory, permissions, audit, review, cost accounting, and receipts. GameCult's thesis sits there: use agents to do bounded work, Bifrost to govern and record it, and CultMesh to move typed state across distributed systems.

12.3 Why this team

The public repos show unusual depth across agents, governance, rendering, audio, distributed state, and social agent interfaces. Bifrost is not just a governance deck; it has an alpha foundation. Epiphany is not merely a chatbot wrapper; it is a typed-state control-plane project. CultMesh is not just a slogan; it has Verse and authority documentation. The caveat is equally important: public depth does not prove customer demand, repeatability, security, or economics.

12.4 Why us

We can give the founder useful capital without forcing the project into a conventional SaaS costume too early. In return, we need proof discipline: Bifrost-first scaling covenants, telemetry, legal gates, and the right to keep capital flowing only if the workflow becomes measurable, governed, and externally repeatable.

Glossary

Agent	An AI model connected to tools and instructions, able to perform tasks rather than only answer questions.
Bifrost	GameCult’s governance, labor, work, reward, receipt, and public-process platform.
CultCache	Typed document storage layer used by GameCult projects.
CultMesh	Distributed typed-state and consensus substrate, organized around Verses.
CultNet	Transport/wire layer for moving typed documents and messages.
Dream	In Epiphany’s roadmap, a public thought artifact that may influence another instance but is not adopted truth.
Epiphany	Persistent agent-control plane for typed memory, role separation, verification, reorientation, and execution.
Face	A repo or project agent’s public/social identity, usually surfaced through Discord or an operator UI.
Heimdall	Planned identity, grants, consent, and capability authority.
Verse	A CultMesh rule-bearing consensus graph with its own authority model and compatibility rules.
Yggdrasil	GameCult’s infrastructure umbrella/hosting context for internal services.
